(Received 13 July 1981/Accepted 28 July 1981)

The effects of dithiothreitol on basal glucose oxidation, hormone-induced lipolysis and insulin receptors in isolated rat adipocytes were studied. Dithiothreitol produced a dose-dependent stimulation of basal glucose oxidation and inhibition of adrenaline-induced lipolysis. Dithiothreitol also inhibited corticotropin-induced lipolysis, but failed to inhibit dibutryl cyclic AMP-induced lipolysis. Dithiothreitol did not inhibit the binding of the β-adrenergic antagonist [3H]dihydroalprenolol to adipocytes. Neither catalase (100 µg/ml) nor EDTA (2 mM) abolished the antilipolytic effect of dithiothreitol. Treatment of isolated adipocytes with 1 mM-dithiothreitol for 20 min at 37°C also caused stimulation of basal glucose oxidation and inhibition of adrenaline-induced lipolysis. A Scatchard plot of insulin binding to control adipocytes was curvilinear. However, treatment of cells with 1 mM-dithiothreitol decreased the curvilinearity of the plot, indicating that only a low-affinity state of the insulin receptors exists in the dithiothreitol-treated adipocytes. These findings suggest that the insulin-like activities of dithiothreitol are mediated through the interaction of dithiothreitol with insulin receptors.

Many chemicals are known to mimic the actions of insulin on adipocytes. Vitamin K₃ (Kuo et al., 1969) and vanadate (Dubya & Kleinzeller, 1980; Shechter & Karlsh, 1980) only stimulate glucose oxidation, whereas concanavalin A, wheat-germ agglutinin (Cuatrecasas & Tell, 1973) and antibodies to insulin receptors (Kahn et al., 1977; Jacobs et al., 1978), which interact with the insulin receptors, stimulate glucose oxidation and inhibit adrenaline-induced lipolysis. Lavis & Williams (1970) reported that dithiothreitol stimulates glucose oxidation and inhibits lipolysis. However, the mechanisms of the insulin-like actions of this chemical are still unknown.

Binding of insulin to solubilized avian erythrocyte receptors induces dissociation of the receptors into subunits (Ginsberg et al., 1976). Jacobs et al. (1979) have found that treatment of solubilized rat liver insulin receptors with dithiothreitol also induces dissociation of the receptors into subunits. These results suggest that dithiothreitol alters the insulin receptors, and the interaction of this chemical with the insulin receptors may induce the insulin-like activities of dithiothreitol.

Experimental

Materials

Bovine serum albumin (non-esterified fatty acid-free, fraction V), crude collagenase (type I), pig insulin, catalase (EC 1.11.1.6), adrenaline, alprenolol, dibutyryl cyclic AMP, dithiothreitol and cytochalasin B were purchased from Sigma. Corticotropin (synthetic 1–24 fragment) was obtained from Daiichi Seiyaku Co., Tokyo, Japan. Hyamine 10X was from Nakarai Chemicals, Kyoto, Japan. Aquasol-2 was from New England Nuclear. 125I-labelled insulin (224 µCi/µg) was from Dainabot Radioisotope Laboratory, Tokyo, Japan. [3H]Dihydroalprenolol (59 Ci/mmol) and D-[U-14C]glucose (255 mCi/mmole) were obtained from The Radiochemical Centre, Amersham, Bucks., U.K.

Methods

Isolation of adipocytes. Adipocytes were isolated from the epididymal fat-pads of Wistar male rats (160–240 g) by the method of Rodbell (1964). The fat-pads were incubated for 60 min at 37°C in Krebs–Ringer bicarbonate medium (119 mM-NaCl/4.8 mM-KCl/1.3 mM-CaCl₂/1.2 mM-KH₂PO₄/1.2 mM-MgSO₄/25 mM-NaHCO₃/30 mg of bovine serum albumin/ml) with 2 mg of collagenase/ml. After digestion, the cells were filtered through nylon mesh and washed three times with buffer.

Glucose oxidation. Isolated adipocytes were incubated for 60 min at 37°C with 0.1 µCi of D-[U-14C]glucose (0.5 mM) and various concentrations of dithiothreitol. The incubations were terminated by...
injecting 0.5 ml of 3 M-H$_2$SO$_4$ and the CO$_2$ formed was collected in 1 ml of Hyamine 10X.

**Lipolysis.** Isolated adipocytes were incubated for 60 min at 37°C with various concentrations of dithiothreitol in the presence of adrenaline, corticotropin or dibutyryl cyclic AMP. Lipolysis was determined by measuring glycerol release into the medium.

$[^3H]$Dihydroalprenolol binding. Isolated adipocytes were incubated for 20 min at 25°C with 0.2 μCi of $[^3H]$dihydroalprenolol and 0, 1 mM- or 3 mM-dithiothreitol. Non-specific binding was calculated from $[^3H]$dihydroalprenolol binding in the presence of 10 mM-alprenolol. At the end of the incubation, 2 ml of ice-cold Krebs-Ringer bicarbonate buffer was added to each vial. The adipocytes were rapidly filtered under vacuum through Millipore SC filters (pore size 8.0 μm), followed by washing with 3 × 1 ml of ice-cold Krebs-Ringer bicarbonate buffer. Each filter was added to 9 ml of Aquasol-2 and counted for radioactivity in a liquid-scintillation counter.

**Dithiothreitol treatment of isolated adipocytes.** Isolated adipocytes were incubated for 20 min at 37°C with 1 mM-dithiothreitol. After incubation, adipocytes were washed with 3 × 10 vol. of dithiothreitol-free Krebs-Ringer bicarbonate buffer.

**Insulin binding.** Control and dithiothreitol-treated adipocytes were incubated with 125I-labelled insulin (0.3 ng) and various concentrations of unlabelled insulin for 30 min at 25°C in a total volume of 0.8 ml. Incubation were terminated by centrifuging 300 μl samples of cell suspension through dinonyl phthalate in plastic tubes as described by Gliemann et al. (1972). The tubes were cut through the oil layer and the cell-bound radioactivities were determined. Specific binding was calculated by subtracting non-specific binding (cell-bound 125I-labelled insulin in the presence of 10 μg of unlabelled insulin) from total binding.

**Results**

**Insulin-like effects of dithiothreitol**

Fig. 1 shows the dose–response relationships of dithiothreitol in the inhibition of adrenaline-induced lipolysis and stimulation of basal glucose oxidation. At 0.1 mM-dithiothreitol, lipolysis was slightly stimulated and basal glucose oxidation was slightly suppressed. Both inhibition of lipolysis and stimulation of glucose oxidation began at about 0.3 mM-dithiothreitol. The shapes of these two dose–response curves were very similar. The concentrations of the chemical required for half-maximal inhibition of lipolysis and half-maximal stimulation of glucose oxidation were 1 mM and 0.78 mM respectively. The stimulation of basal glucose oxidation was not due to the increase of passive glucose transport by dithiothreitol, since this effect was diminished by the presence of 50 μM-cytoskeleton B (Fig. 1).

Dithiothreitol could exert its antilipolytic effect through the β-adrenergic receptor. In order to know whether adrenaline binding to adipocytes is affected by dithiothreitol, the binding of the β-adrenergic antagonist $[^3H]$dihydroalprenolol to isolated adipocytes was measured. Dithiothreitol (up to 3 mM) did not inhibit $[^3H]$dihydroalprenolol binding. Antagonist binding to adipocytes in the presence of 3 mM-dithiothreitol was 125 ± 3.7% (n = 6) of the control value. This stimulation may be due to the protective effect of dithiothreitol on oxidation of $[^3H]$dihydroalprenolol.

Next we examined the effect of dithiothreitol on lipolysis induced by corticotropin and dibutyryl cyclic AMP. As shown in Table 1, lipolysis induced by corticotropin (50 ng/ml) was inhibited by 1 mM-dithiothreitol, whereas 1 mM-dithiothreitol failed to inhibit the lipolysis induced by 3 mM-dibutyryl cyclic AMP.
Table 1. Effects of adrenaline, catalase, EDTA, dibutyryl cyclic AMP and corticotropin on the antilipolytic action of dithiothreitol

Isolated adipocytes were incubated with the additions noted below in the presence or absence of 1 mm-dithiothreitol at 37°C for 1 h. The results are expressed as nmol of glycerol released/h per mg of triacylglycerol, means ± S.E.M. for two sets of triplicate determinations.

AMP. This indicates that dithiothreitol does not exert its action on post-cyclic AMP processes in lipolysis.

Czech et al. (1974) have found that thiols such as cysteine or glutathione stimulate glucose oxidation in adipocytes and that this stimulation results from \( \text{H}_2\text{O}_2 \) generated by thiols, \( \text{Cu}^{2+} \) and \( \text{O}_2^- \), since EDTA or catalase abolishes this effect. In order to determine whether EDTA or catalase has any effect on the antilipolytic action of dithiothreitol, isolated adipocytes were incubated with or without 2 mM-EDTA, 100 μg of catalase/ml and 1 mM-dithiothreitol in the presence of 1 μM-adrenaline. Neither EDTA nor catalase diminished the antilipolytic effect of dithiothreitol (Table 1).

Effects of dithiothreitol treatment of adipocytes on lipolysis, basal glucose oxidation and insulin binding

Isolated adipocytes were treated with 1 mM-dithiothreitol for 20 min at 37°C, then washed with 3 × 10 vol. of dithiothreitol-free buffer. Basal glucose oxidation and adrenaline-induced lipolysis were measured in control and in dithiothreitol-treated adipocytes. Basal glucose oxidation in dithiothreitol-treated adipocytes was increased 64% in comparison with control values (Table 2). Lipolysis induced by 1 μM-adrenaline in dithiothreitol-treated cells was 37% less than in control cells (Table 2). Thus dithiothreitol need not exist in the medium to exert its insulin-like effects.

As shown in Fig. 2, the Scatchard plot of insulin binding to control adipocytes was curvilinear, whereas that to dithiothreitol-treated cells was only slightly curvilinear. This disappearance of the high-affinity state may be due to inactivation of high-affinity receptors or diminution of negative co-operativity. If the former is the case, the number of high-affinity receptors was decreased from 4500 to 1100 sites per cell by treatment with 1 mM-dithiothreitol. If the latter is the case, the dissociation constant at the high-affinity state was

Vol. 200
increased from $5.7 \times 10^{-19}$ M to $2.7 \times 10^{-9}$ M. The Hill coefficient for insulin binding to adipocytes was increased from 0.88 to 0.97, indicating that negative co-operativity was almost diminished by treatment with 1 mM-dithiothreitol.

Discussion

The results of this study show that dithiothreitol has insulin-like effects on adipocytes. This is consistent with the observations of Lavis & Williams (1970) that thiols stimulate basal glucose oxidation and inhibit adrenaline-induced lipolysis. It is possible that inhibition of adrenaline-induced lipolysis might result from the alteration of the adrenaline receptor to decrease the affinity for adrenaline. This possibility was ruled out, since the binding of the $\beta$-adrenergic antagonist $[^3]H$[dihydroalprenolol was not inhibited by dithiothreitol. Furthermore, dithiothreitol, like insulin, inhibited corticotropin-induced lipolysis, but not that induced by dibutyl cAMP. Dose–response curves of inhibition of adrenaline-induced lipolysis and of stimulation of basal glucose oxidation were essentially parallel (Fig. 1). These observations suggest that both the insulin-like effects of dithiothreitol are mediated through the same site.

Czech et al. (1974) reported that stimulation of basal glucose oxidation by thiols was due to $H_2O_2$ formed by $O_2$, $Cu^{2+}$ and thiols, since EDTA or catalase abolished this effect. However, our results showed that neither EDTA nor catalase abolished the antilipolytic effect of dithiothreitol (Table 1). May & de Haën (1979) have found that insulin stimulates intracellular $H_2O_2$ production in rat epididymal fat-cells, suggesting that $H_2O_2$ may act as a second messenger of insulin. Thus it cannot be ruled out that dithiothreitol stimulates endogenous $H_2O_2$ formation; in that case externally added EDTA or catalase would not prevent $H_2O_2$ formation.

Even in the absence of dithiothreitol, basal glucose oxidation was enhanced and arenaline-induced lipolysis was inhibited in washed dithiothreitol-treated adipocytes to the same extent as in the presence of dithiothreitol (Table 2), indicating that dithiothreitol need not be present in the incubation medium to exert its insulin-like effects. At the same time, Scatchard analysis of insulin binding to dithiothreitol-treated adipocytes revealed that treatment of isolated adipocytes with 1 mM-dithiothreitol for 20 min at 37°C caused the disappearance of the high-affinity receptors (Fig. 2). This alteration of the insulin receptors by dithiothreitol could be closely related to the insulin-like effects of dithiothreitol.

Ginsburg et al. (1976) have reported that detergent-solubilized avian erythrocyte insulin receptor is dissociated into four subunits by the addition of insulin. Jacobs et al. (1979, 1980) have found that solubilized rat liver insulin receptors are composed of four subunits, two 135 000-dalton components and two 45 000-dalton components which are joined by disulphide bonds and significant non-covalent interactions. Pilch & Czech (1980) showed that high-affinity fat-cell and liver plasma-membrane insulin-receptor subunits are linked by disulphide bonds. These results and our observations suggest that treatment of adipocytes with dithiothreitol may result in the dissociation of the insulin receptors into subunits that have low affinity for insulin. Such dissociation of the insulin receptors might be a necessary step in evoking the intracellular responses.
